Pre-registered re-analysis of DANDI 001611: at a glance

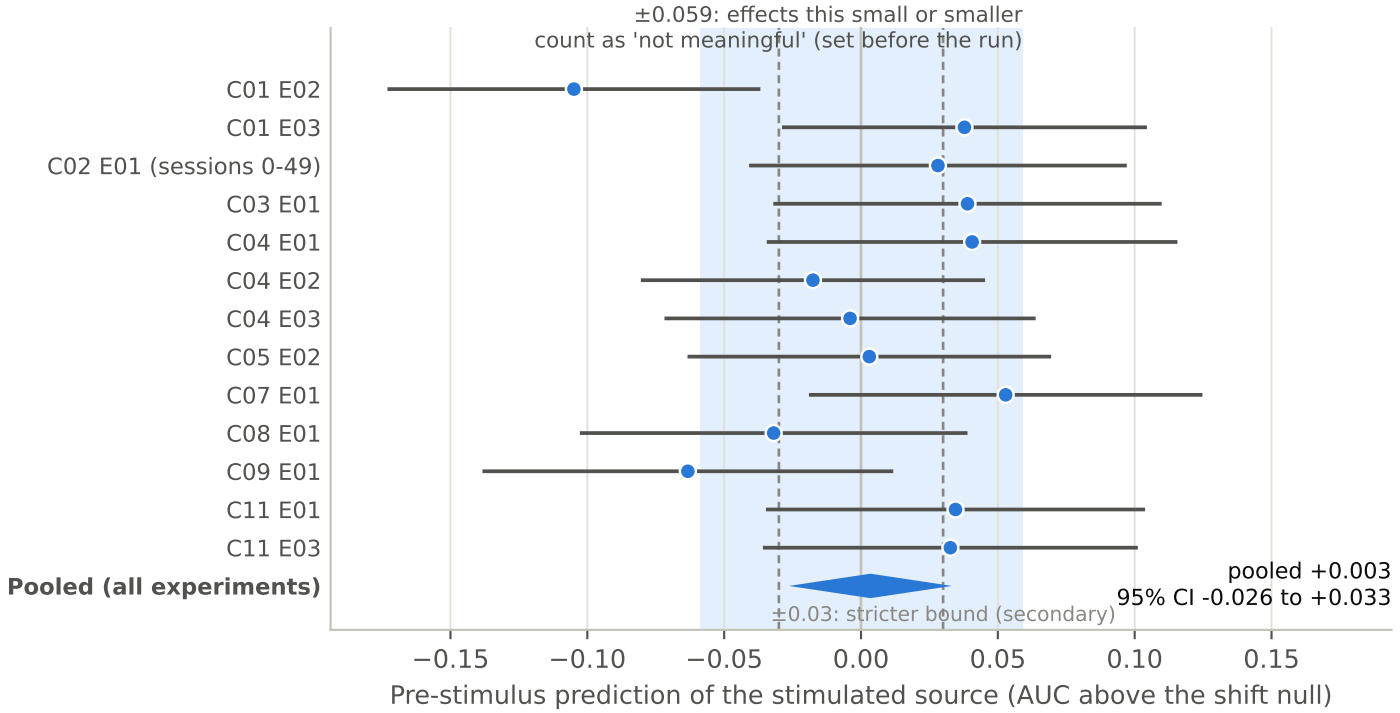

Cedric Cannard and William Reid. From the saved outputs of the held-out run (28 Oct 2026). Each figure's data is attached as CSV

(a) When things happened

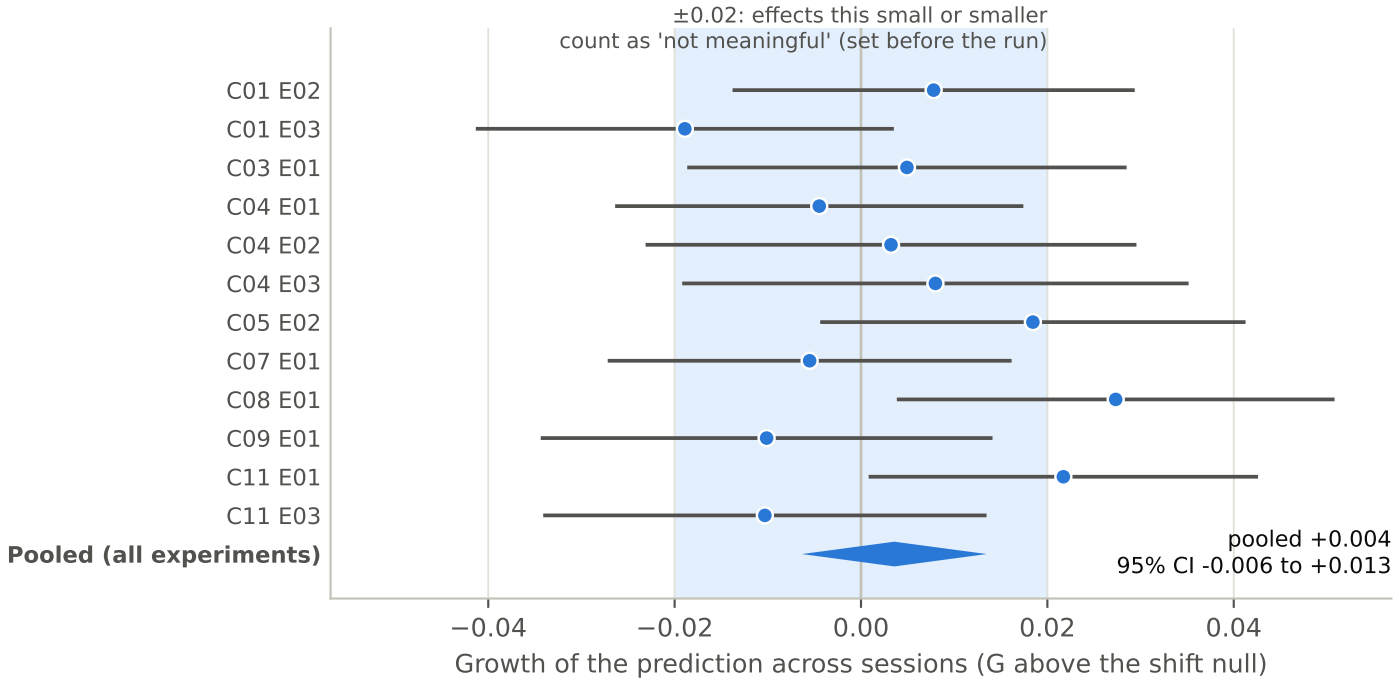

The analysis was frozen by a git tag at 16:19, before the held-out run started at 19:06; the GitHub push (19:15) and the OSF registration (19:51) came during the run, before any output was written (19:58) or displayed (21:13). The recordings are public and had been analyzed before, so the registration is pre-analysis for this pipeline, not pre-data.

(b) Q1: first exposure, per experiment and pooled

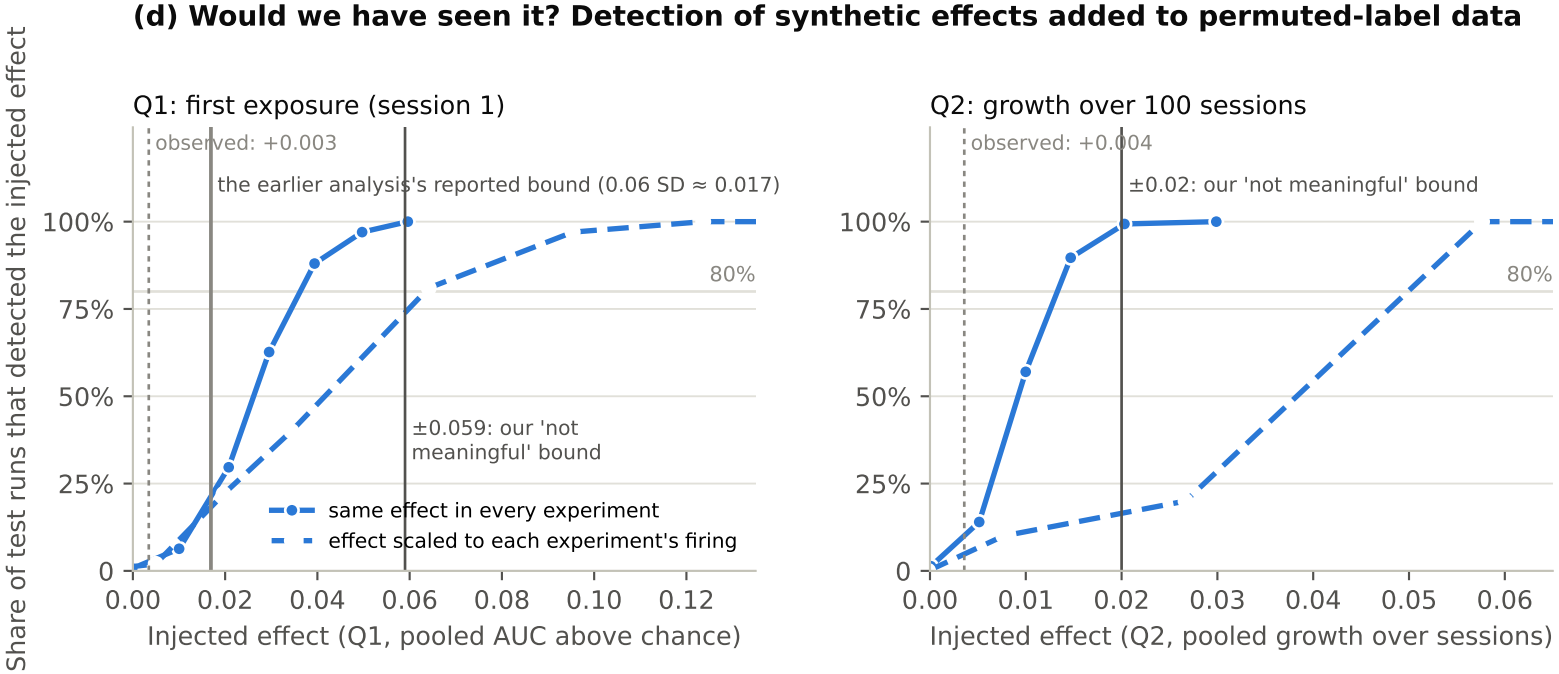

Each dot is one held-out experiment (13 experiments in 9 cultures) with its 95% interval; the diamond is the pooled estimate, +0.003 (95% CI -0.026 to +0.033, p = 0.73), inside the pre-set ±0.059 band, and within the stricter ±0.03 only narrowly (equivalence uses the 90% CI, upper limit +0.027; the 95% CI drawn here reaches +0.033). Result: not detected in this dataset, and bounded.

(c) Q2: growth over 100 sessions, per experiment and pooled

The same construction for growth over 100 sessions (12 experiments in 8 cultures): pooled +0.004 (95% CI -0.006 to +0.013, p = 0.29), inside the pre-set ±0.02 band. Result: not detected in this dataset, and bounded.

(d) Would we have seen it? Detection of synthetic effects added to permuted-label data

Note: sensitivity rests on injected signals only.
The biological positive control (Q2) was itself null and the closed-loop control was not available.

Synthetic effects of known size were added to development-split data with permuted labels before the held-out run; the pipeline found a Q1 effect of about 0.036 (same in every experiment) or 0.063 (scaled to firing) 80% of the time, and a Q2 growth of about 0.013 or 0.050. The earlier analysis's bound (0.06 SD, about 0.017 on this scale) is narrower than our interval because it treats trials as independent, while ours accounts for experiments and cultures (Supplemental Methods S1.2); the two numbers answer different questions.

Sources: results/D/heldout_primary/summary.json, forest_q1.csv, forest_q2.csv; results/B/B2/*power*.csv; PROVENANCE.md; the paper's Supplemental Information (tables S5 and S6). Statements are limited to this dataset and this pipeline; nothing here is a broader claim about the preparation.
